1. Theory

1.1 Multiprocessing:

“Multiprocessing refers to a system that has more than two central processing units (CPUs). Every additional CPU added to a system increases its speed, power and memory. This allows users to run multiple processes simultaneously. Each CPU may also function independently, and some CPUs may remain idle if they don't have anything to process. This can improve the reliability of a system because unused CPUs can act as a backup if technical issues arise.”[1]

Figure 1: Struct of Multiprocessing

1.2 Multithreading:

“Multithreading is a programming technique that assigns multiple code segments to a single process. These code segments, also referred to as threads, run concurrently and parallel to each other. These threads share the same memory space within a parent process. This saves system memory, increases computing speed and improves application performance. For example, if you're working on your computer, you might have multiple browser tabs open while searching the internet. You might also be listening to music through a desktop application at the same time. The internet browser and music application represent two different processes, even though they are operating simultaneously. However, the multiple tabs you have open while browsing the internet represent threads of your internet browser, which is the parent process.”[1]

Figure 2: Struct of Multithreading

2. Procedure:

2.1 My laptop specifications:

I was use virtual box to do the project, first I will The show details for my laptop:

- ⇒ Cores: 4 real core (8 logical core)
- ⇒ Speed: 2.80 GHz
- ⇒ Ram: 8 GB
- ⇒ Rom: 512GB (SSD)
- ⇒ OS: windows 11 pro

For virtual box (virtual machine) I was give it the following:

- ⇒ Cores: 8 cores
- ⇒ Ram: 8 GB
- ⇒ Rom: 20GB
- ⇒ OS: Ubuntu
- ⇒ Programing language: C program
- ⇒ IDE tool: Gedit in Terminal

2.2 achieved the multiprocessing and multithreading

- The Naive approach: for my code first I read the file into array 2D, then built an array of struct that have the unique words and its Frequency, after that the code will check the words in the 2D array if it exists in the unique words array then will increment the frequency, if not then will insert new word to unique words array. Then the program will search for the most 10-word frequency and print them.

After built the Naïve code then I can build the multiprocessing and multithreading dependent on the naïve code:

- ➔ For Multiprocessing code: in my program I was use multiprocessing in calculate the frequency for unique words from array of 17010000 index, so I divide the big array into the process and each process was doing its part, in addition I used in my program pipes to send the data from children to parent, and merge the data from children in the unique array.
- To make new child use `fork()` function from `unistd.h` library.
 - To make pipe use `pipe()` function from `unistd.h` library.
 - To wait use `wait()` function from `sys/wait.h` library.

```
1 #include <stdio.h>
2 #include <stdlib.h>
3 #include <string.h>
4 #include <unistd.h>
5 #include <sys/wait.h>
6
7 #define SizeOfWords 17010000
8 #define StringSize 90
9 #define SizeOfUnique 300000
10 #define NumProcess 2
11
```

Figure 3: The library that I use in multiprocessing

```
42 for (int p = 0; p < NumProcess; p++) {
43     int pid = fork();
44
45     if (pid == 0) { // Child process
46         close(fd[p][0]); // Close reading
47
48         struct words *childFreqWords = (struct words *)malloc(SizeOfUnique * sizeof(struct words));
49         int childNumOfUnique = 0;
50
51         // Calculate the range of words for this process
52         int start = p * (NumOfWords / NumProcess);
53         int end;
54         if (p == NumProcess - 1)
55             end = NumOfWords;
56         else
57             end = start + (NumOfWords / NumProcess);
58
59         // Child process work in its part from the word array
60         for (int i = start; i < end; i++) {
61             int k;
62             for (k = 0; k < childNumOfUnique; k++) {
63                 if (strcmp(array[i], childFreqWords[k].string) == 0) {
64                     childFreqWords[k].freq++;
65                     break;
66                 }
67             }
68             if (k == childNumOfUnique) {
69                 strcpy(childFreqWords[childNumOfUnique].string, array[i]);
70                 childFreqWords[childNumOfUnique].freq = 1;
71                 childNumOfUnique++;
72             }
73         }
74
75         // Write results to pipe
76         write(fd[p][1], &childNumOfUnique, sizeof(int));
77         write(fd[p][1], childFreqWords, childNumOfUnique * sizeof(struct words));
78     }
79 }
```

Figure 4: create process and divide the array

- ➔ For Multithreading for each thread I was find the start index and end index from the main array then in calculate the frequency for unique words. In addition, I use mutex to lock before increment frequency or adding unique word and unlock after that.
- To create new thread use `pthread_create()` function from `pthread.h` library.
 - To join the thread use `pthread_join()` function from `pthread.h` library.
 - To lock data use `pthread_mutex_lock()` function from `pthread.h` library.

```

1 #include <stdio.h>
2 #include <stdlib.h>
3 #include <string.h>
4 #include <pthread.h>
5
6 #define SizeOfWords 17010000
7 #define StringSize 90
8 #define SizeOfUnique 300000
9 #define NumThreads 8
10

```

Figure 5: The library that I use in multithreading

```

25 pthread_mutex_t mutex = PTHREAD_MUTEX_INITIALIZER;
26
27 void *calculateFreq(void *arg) {
28     struct ThreadInfo *data = (struct ThreadInfo *)arg;
29     char **array = data->array;
30     int start = data->start;
31     int end = data->end;
32     struct words *freqWords = data->freqWords;
33     int *numOfUniqueWords = data->numOfUniqueWords;
34     pthread_mutex_t *mutex = data->mutex;
35
36     for (int i = start; i < end; i++) {
37         int k;
38         for (k = 0; k < *numOfUniqueWords; k++) {
39             if (strcmp(array[i], freqWords[k].string) == 0) {
40                 pthread_mutex_lock(mutex); // Lock before modifying
41                 freqWords[k].freq++;
42                 pthread_mutex_unlock(mutex); // Unlock after modification
43                 break;
44             }
45         }
46
47         // If the word is not found in freqWords
48         if (k == *numOfUniqueWords) {
49             pthread_mutex_lock(mutex); // Lock before modifying
50             strcpy(freqWords[k].string, array[i]);
51             freqWords[k].freq = 1;
52             (*numOfUniqueWords)++;
53             pthread_mutex_unlock(mutex); // Unlock after modification
54         }
55     }
56
57     return NULL;
58 }

```

Figure 6: calculate the frequency and lock data in multithreading

2.3 Amdahl's law:

- To calculate the percentage is the serial part of my code I need to use clock from time.h library, in my code all the code is serial expect calculate frequency for unique words so I will calculate the time before it and added it to the time after calculate frequency:

```
sari@sari-VirtualBox: ~/Desktop/sari
sari@sari-VirtualBox:~/Desktop/sari$ time ./05
Top 10 words:
the : 1061396
of : 593677
and : 416629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is Naive approach
The serial time: 2.274390
real    13m18.897s
user    13m17.793s
sys     0m0.997s
sari@sari-VirtualBox:~/Desktop/sari$
```

Figure 7: Serial time in naive approach

- ➔ The serial time is: $2.274390 \times 60 = 136.5s$
- ➔ All execution time: $(13 \times 60) + 19 = 799s$
- ➔ The percentage of the serial time: $(136.5/799) \times 100\% = 17\%$

- The maximum speed up can calculate using Amdahl's law:

The formula is
$$= \frac{1}{S + \frac{(1-S)}{N}}$$

Where S is the percentage of the serial part, and N is the number of cores uses.

From the formula maximum speed up
$$= \frac{1}{17\% + \frac{(1 - 17\%)}{8}} = 3.65$$

So the maximum speed up gain is $3.65 - 1 = 2.65$ then the gain is 265%

- The optimal number of child processes or threads This refers to determining the best configuration of processes or threads to achieve the maximum efficiency or speedup when running the program, considering the hardware and software environment constraints. It ties into performance analysis and how the available CPU cores and other system resources are utilized effectively

For my laptop the optimal number of threads or child process is 8 because I have 8 cores in my laptop

2.4 performance of the 3 approaches:

2.4.1 The Naive approach:

For the naïve approach it's should take more of time than multiprocessing or multithreading, because all the code should work in one code in one task so its take a lot of time, the following figure shows the output of the code and the execution time for naïve approach:

```
sari@sari-VirtualBox: ~/Desktop/sari
sari@sari-VirtualBox:~/Desktop/sari$ time ./05
Top 10 words:
the :      1061396
of :       593677
and :      416629
one :      411764
in :       372201
a :        325873
to :       316376
zero :     264975
nine :     250430
two :     192644

This is Naive approach
The serial time: 2.274390
real    13m18.897s
user    13m17.793s
sys     0m0.997s
sari@sari-VirtualBox:~/Desktop/sari$
```

Figure 8: output of naive approach

Note that the naïve approach take 13min + 19 s , so I expect there is no case take a time more than naïve approach.

2.4.2 2-child process and 2-thread:

The following figures show the output of 2-child process in addition to its execution time:

```
sari@sari-VirtualBox: ~/Desktop/P
sari@sari-VirtualBox:~/Desktop/P$ time ./OS
Top 10 words:
the : 1061396
of : 593677
and : 416629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is 2 child process
real 7m40.767s
user 0m5.212s
sys 0m7.595s
sari@sari-VirtualBox:~/Desktop/P$
```

Figure 9: 2-child process

The following figures show the output of 2-thread in addition to its execution time:

```
sari@sari-VirtualBox: ~/Desktop/T
sari@sari-VirtualBox:~/Desktop/T$ time ./OS
Top 10 words:
the : 1061396
of : 593677
and : 416629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is 2 threads
real 7m39.901s
user 15m5.707s
sys 0m3.859s
sari@sari-VirtualBox:~/Desktop/T$
```

Figure 10: 2-thread

- Note that 2-child process and 2-thread are speed then naïve approach because naïve approach run all the code as one task in on core, but in 2-child process and 2-thread its work part of code in 2core.
- In addition, in 2-child process and 2-thread the code divide the code in calculate the frequency of unique words, so in this part the code run each part in core at the same time, this case make my program faster than naïve.
- For 2-child process and 2-thread, the 2-thread should be faster but note that 2 cases are equal, because in 2-thread code I use mutex to lock data which is take more time and in 2-child process code I was use pipe which don't need lock, so the execution time for the 2 cases is so close together .

2.4.3 4-child process and 4-thread:

The following figures show the output of 4-child process in addition to its execution time:

```
sari@sari-VirtualBox: ~/Desktop/P$ time ./OS
Top 10 words:
the : 1061396
of : 593677
and : 410629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is 4 child process
real 5m29.891s
user 0m4.621s
sys 0m17.255s
sari@sari-VirtualBox:~/Desktop/P$
```

Figure 11: 4-child process

The following figures show the output of 4-thread in addition to its execution time:

```
sari@sari-VirtualBox:~/Desktop/T$ time ./OS
Top 10 words:
the : 1061396
of : 593677
and : 410629
one : 411764
in : 372201

to : 316376
zero : 264975
nine : 250430
two : 192644

This is 6 child process
real 5m24.639s
user 0m5.240s
sys 0m16.570s
sari@sari-VirtualBox:~/Desktop/P$
```

Figure 13: 6-child process

The following figures show the output of 6-thread in addition to its execution time:

```
sari@sari-VirtualBox: ~/Desktop/T
sari@sari-VirtualBox:~/Desktop/T$ time ./05
Top 10 words:
the : 1061396
of : 593677
and : 416629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is 6 threads
real 5m19.356s
user 30m48.039s
sys 0m12.464s
sari@sari-VirtualBox:~/Desktop/T$
```

Figure 14: 6-thread

- 6-child process take 5min24s and 6-thread 5min19s.
- Note that 6-child process and 6-thread are speed then 4-child process and 4-thread because 4-child process and 4-thread run the parallel part code in 4 cores, but for 6-child process and 6-thread its run the parallel part in 6 cores at the same time.
- Note that 6-thread faster then 6-child process which is I expect, but the difference between them not big because in 6-thread code I use mutex to lock data which is take more time and in 6-child process code I was use pipe which don't need lock, so the execution time for the 2 cases is so close together .

2.4.5 8-child process and 8-thread:

The following figures show the output of 8-child process in addition to its execution time:

```
sari@sari-VirtualBox:~/Desktop/P$ time ./05
Top 10 words:
the : 1061396
of : 593677
and : 416629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is 8 child process
real 4m37.815s
user 0m5.390s
sys 0m12.910s
sari@sari-VirtualBox:~/Desktop/P$
```

Figure 15: 8-child process

The following figures show the output of 8-thread in addition to its execution time:

```
sari@sari-VirtualBox:~/Desktop/T$ time ./05
Top 10 words:
the : 1061396
of : 593677
and : 416629
one : 411764
in : 372201
a : 325873
to : 316376
zero : 264975
nine : 250430
two : 192644

This is 8 threads
real 4m23.881s
user 30m17.811s
sys 2m49.073s
sari@sari-VirtualBox:~/Desktop/T$
```

Figure 16: 8-thread

- 8-child process take 4min38s and 8-thread 4min24s.
- Note that 8-child process and 8-thread are speed then 6-child process and 6-thread because 6-child process and 6-thread run the parallel part code in 6 cores, but for 8-child process and 8-thread its run the parallel part in 8 cores at the same time.
- Note that in this case and in my my laptop I reached the maximum utilize of processor because I am using all cores in my laptop (8cose), and I reached maximum speed up.
- Note that 8-thread faster then 8-child process which is I expect, but the difference between them not big because in 8-thread code I use mutex to lock data which is take more time and in 8-child process code I was use pipe which don't need lock, so the execution time for the 2 cases is so close together .

2.4.6 Summary for all approaches:

The following table show all execution time for all approaches:

Number of thread or child process	Naive approach	Multiprocessing	Multithreading
1 (naive)	13min18s	--	--
2	--	7min40s	7min40s
4	--	5min30s	5min37s
6	--	5min24s	5min19s
8	--	4min28s	4min24s

- ➔ Note that all cases faster than naïve approach, so the parallel code is best than serial code
- ➔ In addition, when the number of thread or child process increase then the execution time decrease, this note is exactly compiles with Amdahl's law when we increase the number of cores then the speed up will increase according to the law, and we try this low.

Conclusion

In this project, we explored the power of parallel computing by comparing serial and parallel processing techniques for handling a large data. By implementing multiprocessing and multithreading approaches with increasing numbers of processes and threads, we have shown great importance performance improvements over the naive serial method. Starting from a baseline of 13 minutes and 18 seconds in the serial approach, we progressively reduced execution time to around 4 minutes and 24 second by utilizing all 8 cores of the laptop. The results validated Amdahl's law, showing that as we increased the number of cores, the processing speed improved substantially, with performance gains reaching up to 265%.
